Two-Way

- Pairs (Y_i, X_i) and model

$$Y_i = bX_i + e_i$$

- $H_0 : b = b_0$; (e_i) stochastically independent of (X_i) .
- Deviations

$$D_i(b) = Y_i - b \cdot X_i$$

- Theil's test Statistic

$$C(b) = \sum_{i < j} \text{sign}(D_i(b) - D_j(b))$$

- Under H_0 , $C(b_0)$ is distribution-free.

Effects & Multiple Testing

Two-Way

- ▶ Under H_0 : (X_i) formally independent of $(Y_i - b_0 X_i)$:
 - ▶ Distribution-free when (e_i) are iid with strictly monotone CDF.
 - ▶ Approximate normality

$$C(b_0) \approx_D N(0, \frac{n(n-1)(2n+5)}{18}), \quad n \rightarrow \infty.$$

- ▶ Normalized Statistic:

$$\tilde{C} = \frac{C(b_0)}{\sqrt{\text{Var}_0(S(b_0))}} = 3 \cdot \frac{C(b_0)}{\sqrt{n(n-1)(n+5/2)}}$$

- ▶ Approximate Level- α two-sided test:

$$\text{Reject } H_0 \text{ if } |\tilde{C}| > \tilde{z}_{1-\alpha/2}$$

- ▶ Exact distributions, tests by using *permutation inference*.
- ▶ Asymptotic Relative efficiency under iid Normal (e_i)

$$\text{ARE}(C(b_0), b_{OLS} | \text{bivariate Normal}) = \rho^2 \cdot e(\text{Wilcoxon}, \text{Mean} | \text{univariate Normal}).$$

where

$$\rho = \rho_{\text{Pearson}}(\{X_{(1)}, \dots, X_{(n)}\}, \{1, \dots, n\})$$

Nonparametric Linear Fit with Single Predictor x

- Pairs (Y_i, X_i) and model

$$Y_i = a + bX_i + e_i$$

- Pairwise Slopes

$$b_{ij} = \frac{Y_i - Y_j}{X_i - X_j}$$

- Theil's Slope Estimate

$$\hat{b} = \text{median}_{i < j} b_{ij}$$

- Ordered Pairwise Slopes, $N = \binom{n}{2}$

$$b^1 \leq b^2 \leq \dots \leq b^{N-1} \leq b^N$$

- Theil Confidence Statement

$$b \in (b^{c-}, b^{c+}), \quad c_{\pm} \approx \frac{N}{2} \pm 3_{\alpha/2} \sqrt{\frac{n(n-1)(n+2/5)}{9}}$$

- Intercept estimate (recall $D_i(b) = Y_i - bX_i$):

$$\hat{a} = \text{median}_i D_i(\hat{b}).$$

> abline(lm(foodexp~income,data=engel),lty=2)
> legend("topleft",c('R','LS'),lty=c(1,2))
```

The command `rfit` obtains robust R estimates for the linear regression models, for example (4.1). To examine the coefficients of the fit, use the `summary` command. Critical values and p -values based on a Student t distribution with $n - 2$ degrees of freedom recommended for inference. For this example, `Rfit` used the t -distribution with 233 degrees of freedom to obtain the p -value.

```
> fit<-rfit(foodexp~income,data=engel)
> coef(summary(fit))
```

	Estimate	Std. Error	t.value	p.value
(Intercept)	103.7667620	12.78877598	8.113893	2.812710e-14

12 KTRLLine 1.0—Visual Basic Program for Calculating Robust Nonparametric Estimates of Coefficients Between Variables

LADDER OF POWERS (modified from Velleman and Hoaglin, 1981; Helsel and Hirsch, 2002)				
Use	Power	Transformation	Name	Comment
for (-) skewness		• • •		higher powers can be used
	3	x^3	cube	
	2	x^2	square	
	1	x	original units	no transformation
for (+) skewness	1/2	\sqrt{x}	square root	commonly used
	1/3	$\sqrt[3]{x}$	cube root	commonly used
	0	$\log(x)$	logarithm	commonly used; holds the place of x^0
	-1/2	$-1/\sqrt{x}$	reciprocal root	minus sign preserves order of observations
	-1	$-1/x$	reciprocal	
	-2	$-1/x^2$	reciprocal square	
		• • •		lower powers can be used

Figure 5. The ladder of powers for use in transforming the independent (X) and/or dependent (Y) variables to improve a regression model. (Modified from Helsel and Hirsch, 2002.) All powers except for the reciprocal root and reciprocal square are available in the Kendall-Theil Robust Line software. The line separates transformations for negative (-) and positive (+) skewness.

5. Global income inequality has gone down

Global income distribution in 1800, 1975, and 2015

Income is measured by adjusting for price changes over time and for price differences between countries (purchasing power parity (PPP) adjustment).
These estimates are based on reconstructed National Accounts and within-country inequality measures.
Non-market income (e.g. through home production such as subsistence farming) is taken into account.

Data source: Gapminder

The visualization is available at [OurWorldinData.org](https://ourworldindata.org) where you find more visualizations and research on global development.

Two-Way

- ▶ Would-be coefficients b ($p \times 1$); would-be residuals

$$v(b) = Y - Xb,$$

(note these are not necessarily centered)

- ▶ Normalized ranks $R_i v = \text{Rank}(v_i(b)) / (n + 1)$
- ▶ Rank Discrepancy (convex!)

$$\|Y - Xb\|_\phi = \sum_{i=1}^n \phi(R_i v) v_i$$

- ▶ $\sum_{i=1}^n \phi(\frac{i}{n+1}) = 0$
- ▶ $\phi(t)$ nondecreasing.

- ▶ Examples:
 - ▶ Sign Scores: $\phi(u) = \text{sign}(u - 1/2)$
 - ▶ Wilcoxon Scores: $\phi(u) = \sqrt{12} \cdot (u - 1/2)$
- ▶ Rank estimator (Jaeckel, Jureckova, Hettmansperger-McKean)

$$\hat{\beta} = \text{argmin}_b \|Y - Xb\|_\phi.$$

Properties of Rank-Based Estimator

- ▶ Properties: convex objective, can be solved!
- ▶ Gradient $\nabla_b \|Y - Xb\|_\phi = X^T \phi(Rv(b))$; minimized where:

$$0 = \nabla_{\hat{\beta}} \|Y - X\hat{\beta}\|_\phi \implies 0 = X^T \phi(R(Y - X\hat{\beta}))$$

- ▶ Asymptotic Normality:

$$\hat{\beta}_\phi \sim_{approx} N(\beta, \tau_\phi^2 \cdot (X'X)^{-1})$$

Note: τ_ϕ is *not* Kendall's τ_K .¹

- ▶ Compare standard least squares

$$\hat{\beta}_{ls} \sim_{approx} N(\beta, \text{Var}(e_i) \cdot (X'X)^{-1})$$

- ▶ Asymptotic Relative Efficiency

$$\text{ARE}(\hat{\beta}_\phi, \hat{\beta}_{ls} | F) = \frac{\text{Var}(e_i)}{\tau_\phi^2}$$

- ▶ (Asymptotic) Standard Errors:

$$\text{se}([\hat{\beta}_\phi]_j) = \tau_\phi \cdot [(X'X)^{-1}]_{jj}$$

- ▶ Pro-Forma t -statistics

$$t([\hat{\beta}_\phi]_j) = \frac{[\hat{\beta}_\phi]_j}{\text{se}([\hat{\beta}_\phi]_j)}$$

¹ τ_ϕ defined in (3.19) in Kloeke and McKean.

Linear Regression

Single Predictor
Theil Test
Theil Estimate
Cloud Seeding
rfit Approach
Transformations

- ▶ $H_0 : M\beta = 0$ vs $H_0 : M\beta \neq 0$.
- ▶ Wald Test Statistic

$$\frac{Q(M\hat{\beta}_\phi; M'(X'X)^{-1}M) / \dim(\text{span}(M))}{\tau_\phi^2} > F_{1-\alpha, q, n-p-1}$$

$$Q(m, S) \equiv m'S^{-1}m.$$

- ▶ Recall Jaeckel Discrepancy

$$D(b) = \|Y - Xb\|_\phi$$

$$D(Full) = \min_b D(b);$$

- ▶ Reduced model:

$$X^{Full} = [X^{Red} X^{Extra}], \quad b^{restricted} \equiv [b^{Red} 0]$$

$$D(Red) = \min_{b^{restricted}} D(b^{restricted});$$

- ▶ Drop in dispersion test:

$$RD = D(Red) - D(Full) \quad (\geq 0)$$

- ▶ Significance of Drop in Dispersion

$$F_\phi \equiv \frac{RD/q}{\tau_\phi^2/2} > F_{1-\alpha, q, n-p-1}$$

Analysis of Variance

One-Way
Kruskal-Wallis
Effects & Multiple
Testing
Two-Way

- ▶ Total sample size $n = \sum_{j=1}^k n_j$.
- ▶ Rank R_{ij} of response Y_{ij} among all n observations; ranked without respect to treatment status
- ▶ $R_{.j}$ average rank of j -th treatment group
- ▶ Kruskal-Wallis statistic

$$H = \frac{12}{n(n+1)} \sum_{j=1}^k n_j \left(R_{.j} - \frac{n+1}{2} \right)^2$$

- ▶ Null hypothesis: all observations iid w/o regard to treatment group
- ▶ Distribution-free under null hypothesis; exact distribution available by permutation inference.
- ▶ Approx χ^2 distributed with $k - 1$ degrees of freedom.

Motivation for χ^2 approximation

- Kruskal-Wallis statistic

$$H = \frac{12}{n(n+1)} \sum_{j=1}^k n_j \left(R_{\cdot j} - \frac{n+1}{2} \right)^2$$

- Derivation: under null hyp, each rank is a random sample without replacement from $1, \dots, n$

$$E_0(R_{ij}) = \frac{n+1}{2}.$$

$$\text{Var}_0(R_{i,j}) = (n^2 - 1)/12$$

- The mean rank in a group has a variance $\approx 1/n_j$ as large as any individual rank:

$$\text{Var}_0(\bar{R}_{\cdot j}) = n_j^{-1} \text{Var}_0(R_{i,j})$$

Define $Z_j \equiv \sqrt{n_j}(\bar{R}_{\cdot j} - \frac{n+1}{2}) / \sqrt{\text{Var}_0(\bar{R}_{\cdot j})}$; it is approximately standardized; since $\sum_j Z_j \equiv 0$ the vector $(Z_j)_{j=1}^k$ has only $k - 1$ degrees of freedom.

- Kruskal-Wallis statistic is approximately the sum of k standardized statistics, squared:

$$H = \sum_{j=1}^k (Z_j)^2$$

- Approx χ^2 distributed with $k - 1$ degrees of freedom.

$$\text{Reject } H_0 \text{ for } H \gtrsim (k - 1) + \sqrt{2(k - 1)}\bar{z}_{1-\alpha}$$

Linear Model Parameterization

$$\text{vec}(Y) = X\beta + \text{vec}(e)$$

- $\text{vec}(Y)$, $\text{vec}(e)$ are $n \times 1$ column vectors indexed by pairs (i, j) taken from the array Y in row-major order:

$$(1, 1), (2, 1), \dots, (n_1, 1), (1, 2), (2, 2), \dots, (n_2, 2), \dots, (n_k, k)$$

- X is $n \times k$ matrix with row id's given by pairs (i, j) , $i = 1, \dots, n_j$.

$$X_{(i,1),1} = 1; \quad X_{(i,j),\ell} = 1_{\{\ell=j\}}, \quad \ell = 2, \dots, k$$

- $\beta = (\beta_\ell)$ is $k \times 1$ vector.

$$\beta_1 = \mu_1, \quad \beta_j = \Delta_{j,1}, \quad j = 2, \dots, k.$$

$$\begin{aligned} \text{vec}(Y)_{(i,j),1} &= \sum_{\ell=1}^k X_{(i,j),\ell} \beta_\ell + \text{vec}(e)_{(i,j),1} \\ &= \mu_1 + \Delta_{j,1} + e_{ij} \end{aligned}$$

Analysis of
Variance

One-Way
Kruskal-Wallis
Effects & Multiple
Testing
Two-Way

- ▶ Reduced model: μ_1 arbitrary, $\Delta_{j,1} = 0, j = 2, \dots, k$.
- ▶ Full Model: μ_1 arbitrary, $\max_{j=2,\dots,k} |\Delta_{j,1}|$.
- ▶ Reduction in dispersion $RD_\phi = D_\phi(\text{Red}) - D_\phi(\text{Full})$.
- ▶ Drop in dispersion statistic

$$F_\phi = \frac{RD_\phi / (k - 1)}{\hat{\tau}_\phi / 2}$$

- ▶ $\hat{\tau}_\phi$ estimate of scale.
- ▶ Specifically, for Wilcoxon rank scores write W subscripts, not ϕ .

$$F_W = \frac{RD_W / (k - 1)}{\hat{\tau}_W / 2}$$

Multiple Comparisons

$(1 - \alpha) \cdot 100\%$ CI for effect $\mu_j - \mu_{j'}$:

$$\hat{\Delta}_{jj'} \pm z_{\alpha/2} \cdot \hat{\tau} \cdot \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}}$$

- ▶ There are $\binom{k}{2}$ such CI's.
- ▶ Expected number of failures to cover: $\binom{k}{2} \cdot \alpha$.
- ▶ This includes failures to cover 0, when 0 is true.
- ▶ Familywise error rate FWER =
 $P\{\text{one of the CI's does not cover 0} \mid H_0\}$
- ▶ If $k \gg 14$ and $\alpha = .05$ we expect several (or many) failures.
- ▶ Tukey-Kramer rule instead adjusts CI lengths so that FWER is α . (in some cases; in others, approximately α)
